

# Heuristic Analysis

Pietro Rancati

## Heuristics

Different heuristics utilizing different combination of the available features of the board states (i.e. Available player moves, available opponent moves, moves in common, distance of players from the center etc.) have been implemented and tested. Below are reported and described the three heuristics that performed the best during the tournament (the number of matches has been increased from 10 to 100 to have more stability of the results).

### Custom score 1:

The first custom score is a modification of the improved score discussed in the lecture plus the consideration of the distance of the player position and the opponent position to the center of the board. It is defined as:

$$\text{player\_moves} - \text{opponent\_moves} - \text{centrality}(\text{player}) * \alpha + \text{centrality}(\text{opponent}) * \alpha$$

Where `player_moves` defines the available moves the current player has in the current board state, `opponent_moves` defines the available moves the opponent player has in the current board state, `centrality` defines the distance from a position to the centre of the board (value range between 0 [centre of the board] and 1 [corner of the board]),  $\alpha$  is a factor to weight the centrality based on the state of the board ( $\alpha = (\text{player\_moves} + \text{opponent\_moves}) / 2$ ).

### Custom score 2:

The second custom score is a modification of the improved score discussed in the lecture. It is defined as:

$$\text{player\_moves} - \beta * \text{opponent\_moves}$$

Where `player_moves` define the available moves the current player has with the current board state, `opponent_moves` define the available moves the opponent player has with the current board state, and  $\beta$  is a multiplicative factor (empirically set to 1.5) to make the agent play in a more "aggressive" way, trying to reduce the moves the opponent has.

### Custom score 3:

The third custom score is based on the logic that the player should have more moves in comparison to the opponent and that the opponent should have less moves in comparison to the player. It is defined as:

$$\alpha * (\text{player\_moves} / \text{opponent\_moves}) - \beta * (\text{opponent\_moves} / \text{player\_moves})$$

Where player\_moves define the available moves the current player has with the current board state, opponent\_moves define the available moves the opponent player has with the current board state, and the  $\alpha$  and  $\beta$  multiplicative factors (empirically set to 1. and 2. respectively) represent the importance of the two ratios in the calculation of the score.

## Results and conclusions

The results achieved by the custom scores in the tournament are the following:

| Match #   | Opponent    | AB_Improved |      | AB_Custom |      | AB_Custom_2 |      | AB_Custom_3 |      |
|-----------|-------------|-------------|------|-----------|------|-------------|------|-------------|------|
|           |             | Won         | Lost | Won       | Lost | Won         | Lost | Won         | Lost |
| 1         | Random      | 90          | 10   | 94        | 6    | 96          | 4    | 94          | 6    |
| 2         | MM_Open     | 74          | 26   | 74        | 26   | 74          | 26   | 75          | 25   |
| 3         | MM_Center   | 87          | 13   | 86        | 14   | 83          | 17   | 84          | 16   |
| 4         | MM_Improved | 72          | 28   | 74        | 26   | 74          | 26   | 67          | 33   |
| 5         | AB_Open     | 46          | 54   | 52        | 48   | 56          | 44   | 50          | 50   |
| 6         | AB_Center   | 56          | 44   | 59        | 41   | 55          | 45   | 63          | 37   |
| 7         | AB_Improved | 50          | 50   | 44        | 56   | 52          | 48   | 54          | 46   |
| Win Rate: |             | 67.9%       |      | 69.0%     |      | 70.0%       |      | 69.6%       |      |

As we can see, all the custom scores achieved slightly better results than the improved score discussed in the lecture.

We can derive by the results of custom score 2 and 3, that making the agent playing in a more aggressive way (trying to reduce the number of moves the opponent has) usually pays off and results in a bigger chance of winning.

Also, the score where the centrality factor has been taken into consideration achieves better results, denoting that assuming a more central position during the game is a winning factor.

However, multiple improvements could be introduced:

- Combination of the different heuristics proposed and the introduction of new factors.
- Better selection of the empirical factors ( $\alpha$  and  $\beta$ ) through some more advanced techniques (i.e. utilize genetic algorithms to find the optimal value for each factor).
- Apply different heuristic based on the advancement of game:
  - utilizing a fast early-game heuristic to position the player in an optimal position when entering in the middle/late-game.
  - utilizing a more complex but slow middle/late-game heuristics.

The heuristic I would recommend to use is the custom\_score\_2. Its simplicity is its strength. Although it is pretty simple compared to the other two heuristics, it still achieves the best results. The main reason is that, due to its simplicity, the search tree is explored deeper (1 level deeper than custom\_score and 1/2 levels deeper than custom\_score\_3) and on slow

computer, like the one utilized for the project, where only few levels are explored, it makes the difference. My guess on the isolation game is that the player needs to keep a decent position in the early stages of the game and try to survive the longer during the last stages. The heuristic seems to have these properties, exploring deeper the search tree with more chances to find the "longest survivor" branch.

Moreover the heuristic seems quite stable, achieving consistently good result against all the other players.
